

Konstantinos Karagiorgos

**Using different sources
of rain data to model
urban flooding**

Introduction

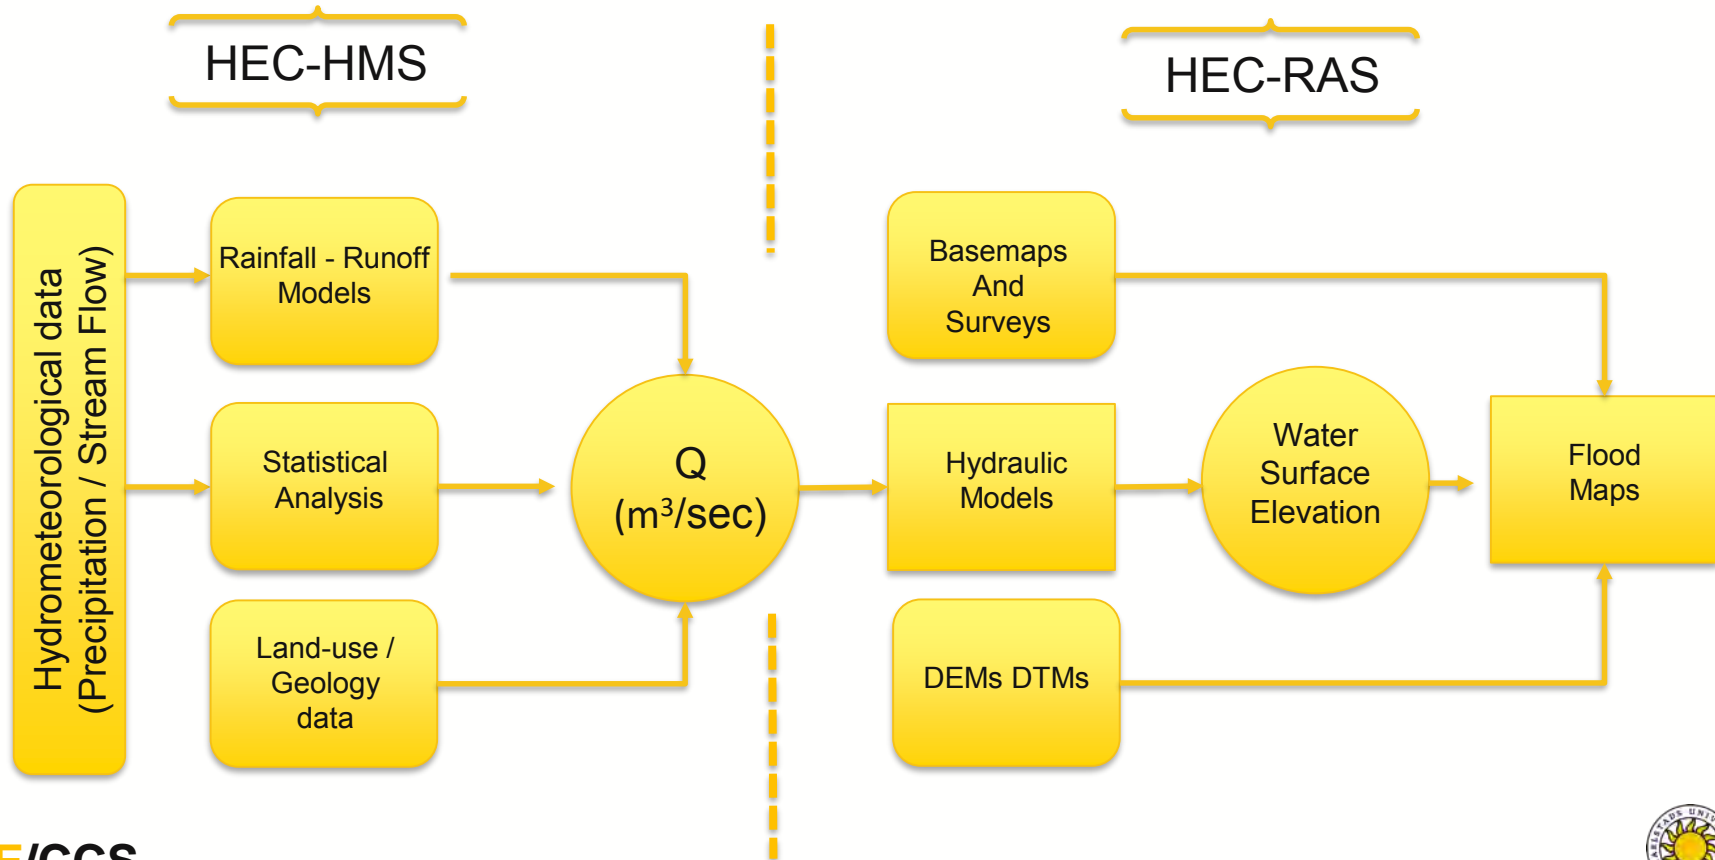

- Floods
 - Extremely complex phenomenon to model

- Key challenges
 - 1. Data
 - 2. Methods
 - 3. Applications

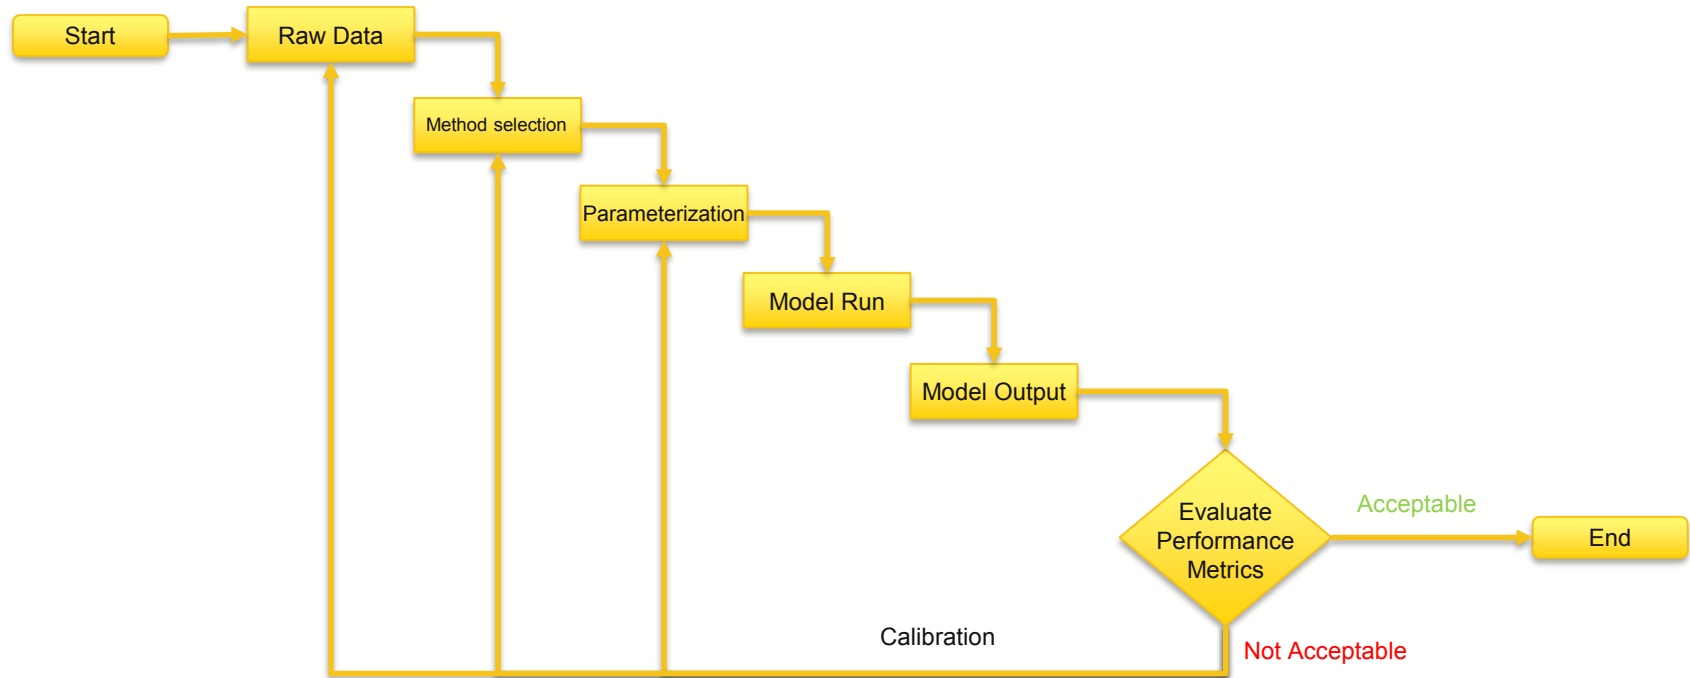

Introduction – flood hazard analyses

- Why?
 - Describe areas of high and low flood risk
 - Produce a range of probabilities described by return period
- How?
 - Hydrology
 - How much water?
 - Hydraulic modelling
 - Where does the water go?

Model - workflow

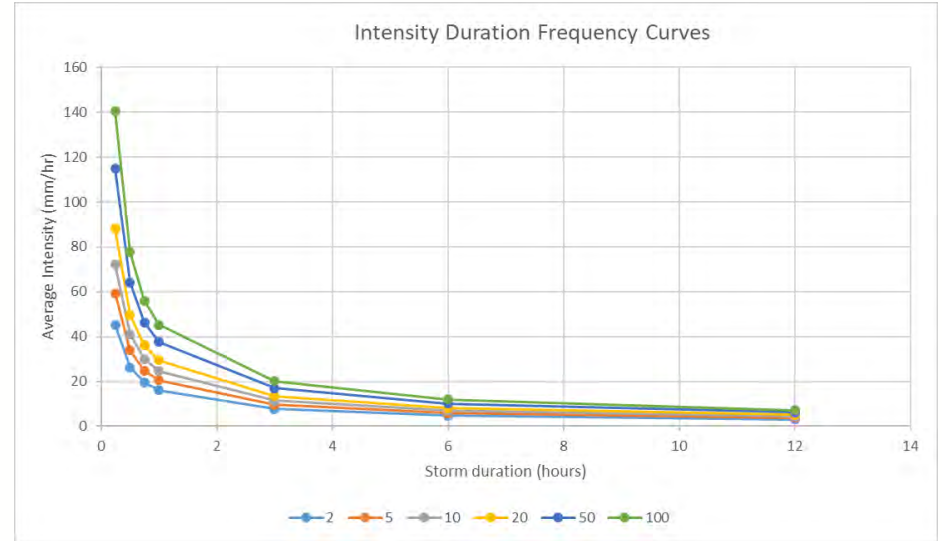

Model - calibration

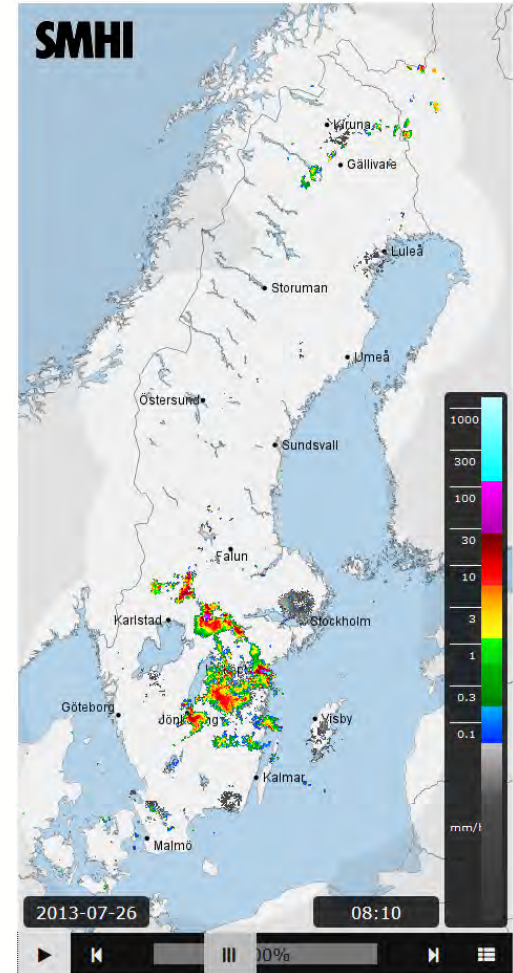

Model – Calibration / Validation

- Event based models
 - 3 Events Calibration
 - 2 Events Validation
- Probabilistic models

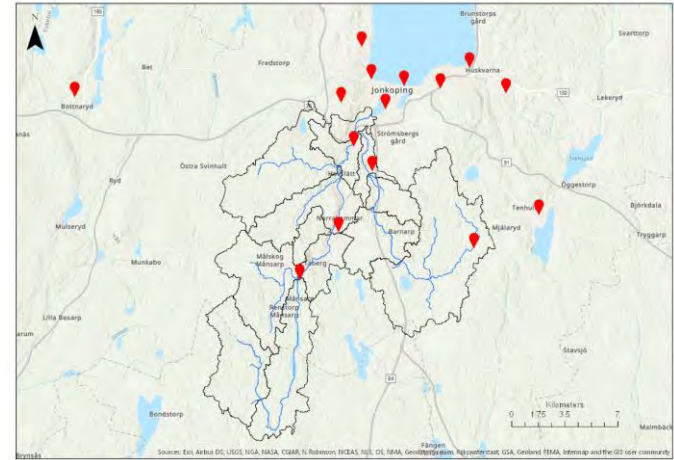

Data - Radar

- Swedish Meteorological and Hydrological Institute
- Sweden
- 2008 – Current
- *.png - *.tif
- ArcMap – HEC-DSS
- Grid format - 5 minutes time step

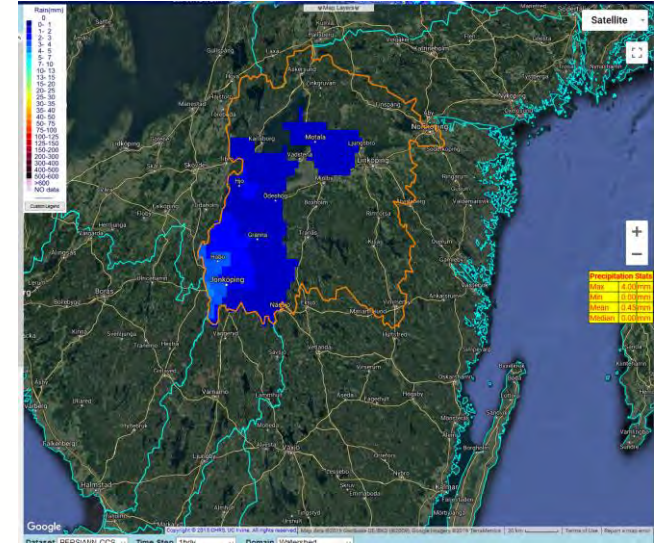

Data – Time Series

- Jönköping Municipality
- 20 Stations
- 1990 – Current
- *.csv
- time – series analysis
- Interpolation - Grid files

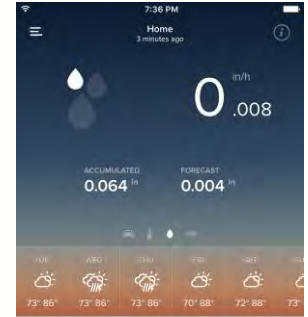

Data – Satellite data

- Center for Hydrometeorology and Remote Sensing (CHRS) - University of California
- World
- 2003 – Current
- *.tif
- Arcmap – HEC-DSS
- Grid format – 1hour time step

Data – NetAtmo

- Personal Weather Station
- Cheap / User-friendly / grown rapidly network
- NetAtmo platform (+ Wundermap etc)
- 5min interval
- Measurement range $0.2 - 150 \text{ mm h}^{-1}$
- Comparison with gauge data (Karlstad airport)

Next Steps

- Flood hazard maps
 - Event 26/07/13
 - Return periods 2/5/10/20/50/100 years
- Vulnerability analysis
 - Stage-Damage Curves
 - SoVI
- Risk Maps
 - Insurance / Decision makers / Population

Tack!
